

Dr.-Ing. Sascha Heitkam,

Institute for Process Engineering and Environmental Technology

Lecture 10: Foam stability

Structure

- Review lecture 9
- Film rupture
- Coarsening
- Stability testing
- Defoaming

Rheometer

- Measure relation between strain (rate) and stress
- Well defined geometry
- → analytical solution of stress / strain distribution
- Avoid wall slip! → etching grooves, sandpaper

Light refraction

- Thick lamellas – partially reflected, CBF lamellas – no reflection
- Light is refracted/reflected by Plateau borders

Foam height

- Automated measurement of foam height, using transmittency
- Commercialized in foam test devices

[Hoang et al. 2020]

Optical measurement of foam surfaces

Liquid fraction $\leftrightarrow$ resistivity

- Gas has zero conductivity – current is transported by Plateau border network
- Conductivity is a good measure for liquid fraction

$$R \sim \frac{1}{\sigma} \frac{L}{A}$$

$$\frac{\sigma}{\sigma_{liquid}} = \varphi_l \frac{2(1 + 12\varphi_l)}{6 + 29\varphi_l - 9\varphi_l^2}$$

$$\varphi_l = \sigma \frac{3(1 + 11\sigma)}{1 + 25\sigma + 10\sigma^2}$$

[Feitosa et al. 2005]

Radiography

- Radiation source and detector
- Radiation is attenuated by measurement object → Beer-Lambert law

X-ray tomography

- High-energetic radiation from synchrotron source
- Very precise measurement requires long exposure
- → Small measurement volume, small velocities

[Raufaste et al. EPL 2015]

Xray-Particle Tracking Velocimetry

- 3D-printed particles with metal content, sticking in foam
- Tracking of particles yields velocity and vorticity of the foam flow

[Lappan et al. 2020]

Exercise: Attenuation

- Attenuation of different foam samples
- X-ray, 150 keV: "NIST Standard Reference Database 126" →
- (a) Shaving foam, 10 cm thickness, $D_b=0.1\text{mm}$, $\varphi_l=10\%$

$$\frac{I}{I_0} = e^{-(\sigma s)} = e^{-(0.0575 / \text{cm} \cdot 10 \text{ cm} \cdot 10\%)} = 94.4\%$$

$$\frac{\Delta I}{I_0} = 5.6\%$$

$$\frac{\Delta I}{I_0} = 97.6\%$$

$$\frac{\sigma}{\rho} = 0.0575 \frac{\text{cm}^2}{\text{g}} \rightarrow \sigma = 0.0575 \frac{1}{\text{cm}}$$

$$\sigma_{\text{neutron}} = 3.74 \frac{1}{\text{cm}}$$

- (b) Plateau border (transversal oriented) of soap foam, $D_b=5\text{mm}$, $\varphi_l=0.1\%$

$$r = R_e \sqrt{\frac{\varphi_l}{0.72}} \approx 0.093 \text{ mm}$$

Decoration theorem: $\varphi_l \approx 0.72 \frac{r^2}{R_e^2}$

$$\frac{I}{I_0} = e^{-(\sigma r)} = e^{-(0.0575 / \text{cm} \cdot 0.0093 \text{ cm})} = 99.946\%$$

$$\frac{\Delta I}{I_0} = 0.054\%$$

$$\frac{\Delta I}{I_0} = 3.5\%$$

Neutron radiography of liquid fraction

- Forced drainage setup in neutron radiography
- Plateau borders visible
- Liquid fraction can be quantified

[Heitkam et al. 2018]

Optical velocity measurement

- Consecutive images with defined time shift Δt analysed
- A: Segmentation $\rightarrow$ shift of each bubble center position $\Delta x_i \rightarrow$ velocity $u_i = \Delta x_i / \Delta t$
- B: PIV-Algorithm $\rightarrow$ **interrogation windows** $\rightarrow$ correlation of consecutive images $\Delta x(x,y)$ velocity $u = \Delta x / \Delta t$

[B. Dollet]

Structure

- Review lecture 9
- Film rupture
- Coarsening
- Stability testing
- Defoaming

Foam stability

- Two modes of foam destruction:
- A: Coalescence / Film rupture
→ Increased bubble size / reduced foam volume

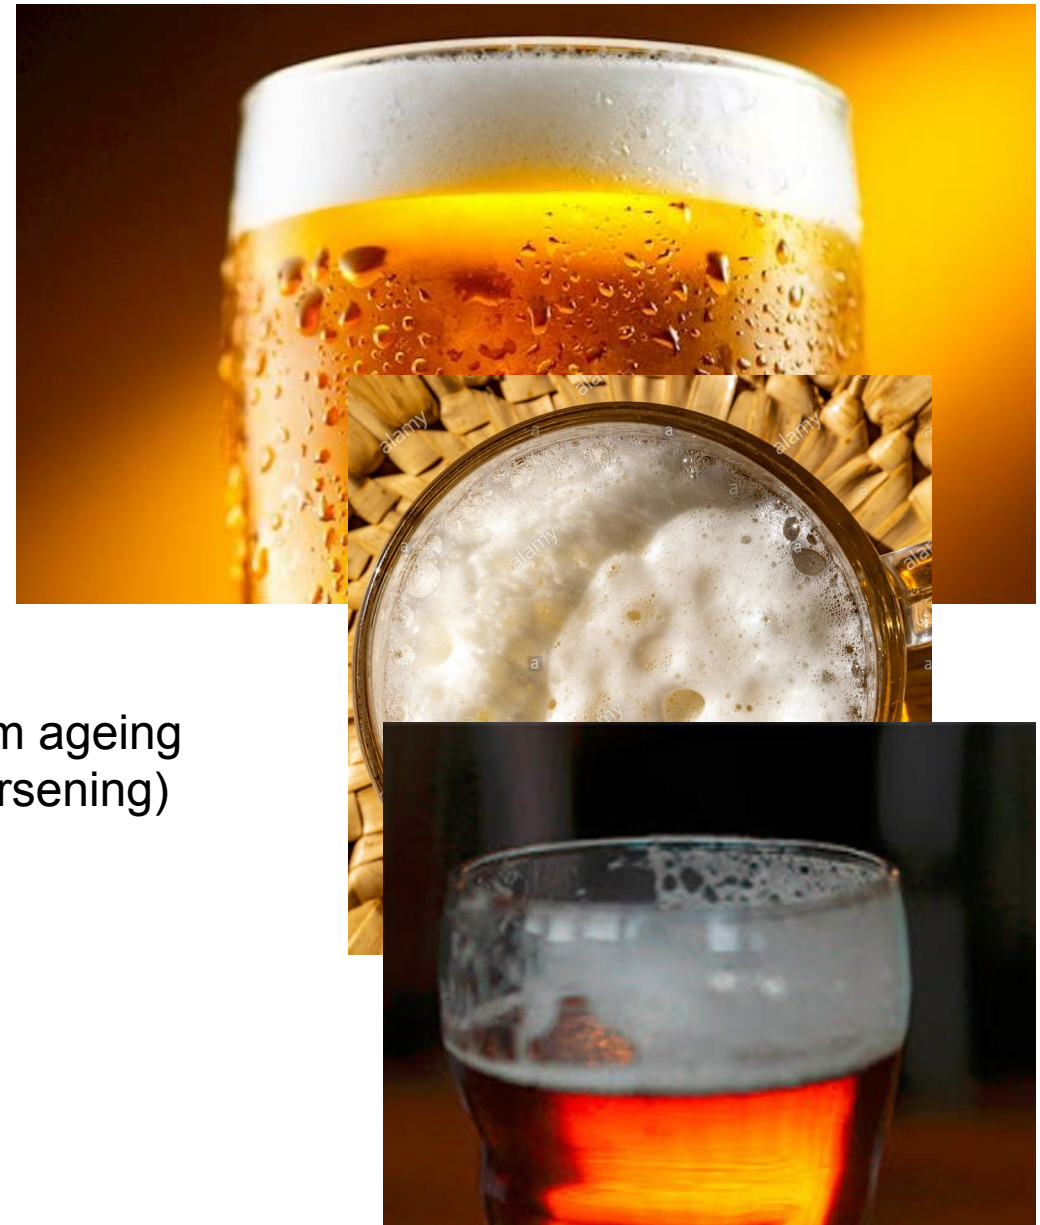

- B: Coarsening (Ostwald ripening)
→ increased bubble size

T2 process

Foam ageing
(coarsening)

L5: disjoining pressure

- Disjoining force is a function of film thickness
- 3 contributions:
 - Electrostatic repulsion $\sim \exp(-h)$
 - Dipol (Van-der-Waals) $\sim h^{-3}$
 - Steric (collision)
- Undisturbed superposition

Film stability

- 2 stable regions:
- Common Black Films ($h \sim 50 \text{ nm}$)
- Newton Black Films ($h \sim 4 \text{ nm}$)

Film stability

- Film stretching → locally lower surface coverage
- Marangoni effect cures weak spots

Film stability

- Sufficient surface coverage required for stable foam
- Required concentration typically near CMC

Film rupture

- Several possible mechanisms:

Film rupture velocity

- Fast motion of interface
- Thickening of edge
- Production of droplets

© Youtube, Cavitar Ltd

Film rupture velocity

- Surface tension pulls the hole open

$$\frac{d(M u)}{dt} = F = 2 \gamma 2 \pi a, u = \frac{da}{dt}$$

$$M = \rho_l \pi a^2 h$$

$$u = \sqrt{\frac{2\gamma}{\rho_l h}} \xrightarrow{h \approx 50 \text{ nm}} u \sim 40 \text{ m/s} \xrightarrow{R_e \approx 1 \text{ mm}} t \sim 25 \text{ ms}$$

Film rupture time scale

- Young, unstable foam: Poisson distribution for rupture rate
- Old, stable foam: rupture avalanches
- → no clear scaling law (liquid fraction, film thickness, disjoining pressure?)

[Müller & di Meglio, 1999]

Rupture avalanche

- Film rupture might release droplets
- Impact of droplets causes next film rupture
- Alternatively: Relaxation causes film stretching

Structure

- Review lecture 9
- Film rupture
- Coarsening
- Stability testing
- Defoaming

Ostwald ripening

- Ostwald ripening for bubbly liquid

$$\Delta p = \frac{2\gamma}{R_1} - \frac{2\gamma}{R_2}$$

High pressure Low pressure

Ostwald ripening vs. von Neumann-Mullins coarsening

- Ostwald ripening for bubbly liquid
- Von Neumann-Mullins coarsening for dry foam

$$\Delta p = \frac{2\gamma}{R_1} - \frac{2\gamma}{R_2}$$

$$\Delta p = 2\gamma H_{i,j}$$

Low pressure

High pressure

Gas solubility

- Solubility depends on (partial) pressure
- Partial pressure depends on composition of gas mixture $p_i = p \frac{n_i}{n} \rightarrow$ neglected here
- Henry's law: $c = k_H p$
- Henry constant k_H depends on material and temperature

Gas diffusion

- Equilibrium over liquid lamella (steady state)
- Neglecting transport to/from the interface (pure gas)

$$\frac{\Delta c}{h} = \frac{\partial c}{\partial x} = -k_H \frac{p_1 - p_2}{h}$$

Molecular flux through Area A (Fick's law):

$$\frac{\Delta n}{\Delta t} = -D_f A \frac{\partial c}{\partial x}$$

$$p_0 V = n R T$$

Volumetric flux through Area A:

$$\frac{\Delta V}{\Delta t} = \frac{\Delta n R T}{\Delta t p_0} = -D_f A \frac{\partial c}{\partial x} \frac{R T}{p_0}$$

$$\Delta V = \Delta n \frac{R T}{p_0}$$

Gradient over lamella:

$$\frac{\Delta V}{A \Delta t} = D_f k_H \frac{p_1 - p_2}{h} \frac{R T}{p_0}$$

Effective diffusion coefficient D_{eff}

$$\frac{\Delta V}{A \Delta t} = D_f k_H \frac{p_1 - p_2}{h} \frac{R T}{p_0} = D_{\text{eff}} H_{1,2} \rightarrow$$

$$D_{\text{eff}} = D_f k_H \frac{2\gamma R T}{h p_0}$$

$$\Delta p = 2\gamma H_{i,j}$$

$$[D_{\text{eff}}] = \text{m}^2/\text{s}$$

Growth of bubble size

- Small bubbles → small number of neighbours → convex, high mean curvature $H_{i,j}$
- Small bubble vanish, larger bubbles grow

- Average bubble size evolution:

$$R = R_0 \sqrt{1 + \frac{t}{t_c}}$$

$$t_c \approx \frac{\langle V(t=0) \rangle^{2/3}}{b D_{eff}}, b \approx 1$$

$$\frac{\Delta V}{A \Delta t} = D_{eff} H_{1,2}$$

Influence of type of gas

- Solubility k_H depends on gas
- Diffusion D_f depends on gas
- $C_2F_6 \rightarrow$ very stable foam
- $N_2, CO_2 \rightarrow$ fast coarsening

$$\frac{\Delta V}{A \Delta t} = D_{eff} H_{1,2} \rightarrow D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0}$$

Influence of surfactant

- Surface tension depends on surfactant
- Film thickness depends on surfactant
- Protein surfactant → large h → stable foam
- Ionic surfactant → small h → fast coarsening

$$\frac{\Delta V}{A \Delta t} = D_{eff} H_{1,2} \rightarrow$$

$$D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0}$$

Influence of Liquid fraction

- Liquid accumulated in Plateau borders
- Thicker Plateau borders reduce effective lamella area

$$\text{Model 1} \quad a(\varphi_l) = 1 - \sqrt{\frac{\varphi_l}{\varphi_l^*}}$$

$$\text{Model 2} \quad a(\varphi_l) = \left(1 - \sqrt{\frac{\varphi_l}{\varphi_l^*}}\right)^2$$

$$\frac{\Delta V}{A \Delta t} = D_{eff} H_{1,2} \rightarrow D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0} a(\varphi_l)$$

Exercise: time scale for Coarsening

- Time for a foam to double its average bubble radius by coarsening?
- SDS foam, 50 nm film thickness,
- A) 0.1 mm bubble radius, CO₂, 10 % liquid fraction

- CO₂: $k_H = 3.4 \times 10^{-4} \frac{\text{mol}}{\text{L bar}}$ $D_f = 1.9 \times 10^{-9} \frac{\text{m}^2}{\text{s}}$

- B) 5 mm bubble radius, C₂F₆, 0.1 % liquid fraction

- C₂F₆: $k_H = 5.8 \times 10^{-5} \frac{\text{mol}}{\text{L bar}}$ $D_f \approx 1.2 \times 10^{-9} \frac{\text{m}^2}{\text{s}}$

$$R = R_0 \sqrt{1 + \frac{t}{t_c}}$$

$$t_c \approx \frac{\langle V(t=0) \rangle^{2/3}}{b D_{eff}}, b \approx 1$$

$$D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0} a(\varphi_l)$$

$$a(\varphi_l) = 1 - \sqrt{\frac{\varphi_l}{\varphi_l^*}}$$

Gas constant: $R = 8.314 \frac{\text{J}}{\text{mol K}}$

Exercise: time scale for Coarsening

- Time for a foam to double its average bubble radius by coarsening?
- SDS foam, 50 nm film thickness,
- A) 0.1 mm bubble radius, CO₂, 10 % liquid fraction

• CO₂:

$$k_H = 3.4 \times 10^{-4} \frac{\text{mol}}{\text{L bar}} = 3.4 \times 10^{-6} \frac{\text{mol}}{\text{m}^3 \text{Pa}} \quad D_f = 1.9 \times 10^{-9} \frac{\text{m}^2}{\text{s}}$$

$$a(\varphi_l) = 1 - \sqrt{\frac{\varphi_l}{\varphi_l^*}} = 0.47$$

$$D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0} a(\varphi_l) = 9 \times 10^{-11} \frac{\text{m}^2}{\text{s}}$$

$$t_c \approx \frac{\langle V(t=0) \rangle^{2/3}}{b D_{eff}} = 290 \text{ s}$$

$$\frac{R}{R_0} = 2 = \sqrt{1 + \frac{t}{t_c}} \rightarrow t = 3 t_c = 870 \text{ s} = 14 \text{ min}$$

Exercise: time scale for Coarsening

- Time for a foam to double its average bubble radius by coarsening?
- SDS foam, 50 nm film thickness,
- B) 5 mm bubble radius, C₂F₆, 0.1 % liquid fraction

• C₂F₆: $k_H = 5.8 \times 10^{-5} \frac{\text{mol}}{\text{L bar}} = 5.8 \times 10^{-7} \frac{\text{mol}}{\text{m}^3 \text{Pa}}$ $D_f \approx 1.2 \times 10^{-9} \frac{\text{m}^2}{\text{s}}$

$$a(\varphi_l) = 1 - \sqrt{\frac{\varphi_l}{\varphi_l^*}} = 0.95$$

$$D_{eff} = D_f k_H \frac{2\gamma RT}{h p_0} a(\varphi_l) = 1.9 \times 10^{-11} \frac{\text{m}^2}{\text{s}}$$

$$t_c \approx \frac{\langle V(t=0) \rangle^{2/3}}{b D_{eff}} = 3.4 \times 10^6 \text{s}$$

$$\frac{R}{R_0} = 2 = \sqrt{1 + \frac{t}{t_c}} \rightarrow t = 3 t_c = 10^7 \text{s} = 100 \text{ days}$$

Air: 12 days

Self-similar regime

- Coarsening process leads to increasing average bubble size $\langle V \rangle$
- Eventually reaching self-similar regime:
- → Identical topology, identical size distribution $P(V/\langle V \rangle)$

Influence on coalescence?

- Traces of C6F14 sufficient
- C6F14 also reduces coalescence (film rupture)
- Film formation at interface???

Fluorocarbon Vapors Slow Down Coalescence in Foams

Katja Steck,* Martin Hamann, Sébastien Andrieux, Pierre Muller, Patrick Kékicheff, Cosima Stubenrauch, and Wiebke Drenckhan

Application of C6F14

- Traces of C6F14 sufficient
- Partial pressure at 25°C: 218 mmHg = 29kPa

Structure

- Review lecture 9
- Film rupture
- Coarsening
- Stability testing
- Defoaming

Relevance of film stability

- Food texture
- Cleaning
- Industrial processes
- → requirement of stability test

Bartsch test

- Shaking with defined frequency, time
- Measurement of resulting foam volume

Foamability test

Bikerman standardized test

- Constant gas flow rate through a porous plate
- Measurement of (steady) resulting foam height

Fig. 3.6. Determination of the liquid volume in foam during bubbling. 1 is the nitrogen reservoir; 2 is the flow meter; 3 is the porous plate; 4, 4 and 5, 5 are the boundaries of the foam column; 6 is a buret; and 7 and 8 are manometers (after reference ⁴⁹).

[Bikerman, Foams, 1973]

Bikerman standardized test

- Equilibrium between vertical convection and drainage flow
- Drainage equation yields critical gas velocity

Foamability test

- Motivated by Bikerman test (same setup)
- Observe growth rate and final height
- Strongly influenced by humidity!

[Li et al, J. Mineral. Process, 2009]

Foamability vs. Foam stability

- Constant gas flow: foamability
- Gas flow switched off – foam stability

Commercial devices

- Controlled gas flow rate, volume
- Foam height measurement
- Bubble size measurement
- Liquid fraction distribution
- Different manufacturer
- Automated, reproducible
- Measures foamability and foam stability

Examples of foamability / foam stability

- Foam height of milk foam
- Different pre-treatment, different temperatures
- Gas flow switched off after 18 sec

[Oetjen et al., 2014]

Examples of foam stability

- Bubble size measurement

[Oetjen et al., 2014]

Foam stability under zero-g

- Long term experiment on the ISS
- Stable foam at high liquid fraction, zero drainage
- Precise measurement of coarsening

© ESA, BUOC

Structure

- Review lecture 10
- Film rupture
- Coarsening
- Stability testing
- Defoaming

Typical applications

- Removal of CO₂ from biogas
- Packed bed of wrinkled bodies → foam generation
- Foam blocks device, reduces efficiency
- Scrubbing solution contains defoaming agent
- → film rupture

Types of Antifoams

- Additives to the solution that prevent foam formation and/or destroy foam
- Solid antifoams
 - silica, wax, polymer
- Liquid antifoams
 - triglycerides
 - silicon oils, mineral oils
- Solid+liquid antifoams
 - oil + particles

Silica particles

100 nm

Oil emulsion

30 μm

Oil+particles

1 μm

Film stabilisation by particles

- Depending on contact angle
- Hydrophilic particles ($\theta < 90^\circ$) reach to stable position

	Endogenous Particle Stabilization (EPS)	Solid Particle Stabilization (SPS)	Oxide Network Particle Stabilization (ONS)
Barrier Effect: Schematic	 Particles develop from the melt during solidification and are part of the microstructure.	 Ceramic particles are deliberately added to the melt.	 Oxides are accidentally produced during melt atomization.
Barrier Effect: Experimentally	Coarse  100 μm Fine  20 μm	Two approaching interfaces  100 μm Cell wall  100 μm	 100 μm  100 μm

[Körner et al., 2005]

Film rupture by particles

- Depending on contact angle
- Hydrophobic particles ($\theta > 90^\circ$)
- Cause de-wetting and film rupture

[Garret, Defoaming, 1992]

Film rupture by particles

- Shape of particles can support film rupture
- Sharp edges prevent stable situations
- Relevant e.g. for mineral particles

[Garret, Defoaming, 1992]

Film rupture by liquids

- Droplets adsorb at water-air interface
- Droplet bridges film
- Either dewetting or bridge-stretching
- Depending on contact angles
- Depending on drop rheology

Film rupture by compounds

- Particles support rupture of air-water-oil film
- Oil ruptures film by de-wetting

[Garret, Defoaming, 1992]
